Mechanical Vibration Solved Examples: A Comprehensive Guide for Engineering Students

Mechanical vibration solved examples are essential for understanding the fundamental principles of vibratory motion in mechanical systems. Vibration analysis plays a crucial role in designing durable structures, machinery, and components by predicting how they respond under dynamic loads. This article provides detailed, step-by-step solved problems that help students and engineers grasp the concepts of free and forced vibrations, damping, and resonance. Whether you're preparing for exams or applying vibration analysis in real-world scenarios, these examples serve as valuable learning tools.

Understanding the Basics of Mechanical Vibrations

Before diving into solved examples, it's important to understand key concepts in mechanical vibrations:

- **Free Vibrations:** Oscillations occurring without external force after an initial disturbance.
- **Forced Vibrations:** Oscillations caused by external periodic forces.
- **Damping:** The effect of resistive forces (like friction or dashpots) that reduce vibration amplitude over time.
- **Resonance:** The phenomenon where the frequency of external force matches the natural frequency, causing maximum amplitude.

Understanding these principles is vital for solving vibration problems effectively.

Sample Problem 1: Free Vibration of a Single Degree of Freedom System

Problem Statement:

A mass of 10 kg is attached to a spring with a stiffness of 200 N/m. The system is displaced from its equilibrium position by 0.05 m and released. Determine:

- The natural frequency of vibration.
- The period of vibration.
- The maximum velocity during vibration.
- The maximum acceleration during vibration.

Solution:

Step 1: Find the natural frequency (ω_n)

The natural frequency is given by:

$$\omega_n = \sqrt{k/m}$$

where:

- $k = 200 \text{ N/m}$
- $m = 10 \text{ kg}$

Calculation:

$$\omega_n = \sqrt{(200 / 10)} = \sqrt{20} = 4.472 \text{ rad/sec}$$

Step 2: Find the period (T)

Period is related to natural frequency:

$$T = 2\pi / \omega_n = 2\pi / 4.472 = 1.404 \text{ sec}$$

Step 3: Determine maximum velocity ($v_{\max}$)

Maximum velocity occurs at equilibrium position and is given by:

$$v_{\max} = \omega_n \times A$$

where $A = 0.05 \text{ m}$ (initial displacement)

$$v_{\max} = 4.472 \times 0.05 = 0.224 \text{ m/sec}$$

Step 4: Determine maximum acceleration ($a_{\max}$)

Maximum acceleration occurs at maximum displacement and is given by:

$$a_{\max} = \omega_n^2 \times A$$

$$a_{\max} = (4.472)^2 \times 0.05 = 20 \times 0.05 = 1 \text{ m/sec}^2$$

Sample Problem 2: Damped Free Vibration

Problem Statement:

A 5 kg mass attached to a spring with stiffness 600 N/m undergoes damping with a damping coefficient of 20 Ns/m. The system is displaced by 0.02 m and released. Find:

- The damping ratio (ζ).
- The damped natural frequency (ω_d).
- The time period of damped vibration.
- The maximum amplitude after 3 seconds if initial amplitude is 0.02 m.

Solution:

Step 1: Calculate the undamped natural frequency (ω_n)

$$\omega_n = \sqrt{k/m} = \sqrt{600 / 5} = \sqrt{120} = 10.954 \text{ rad/sec}$$

Step 2: Calculate damping ratio (ζ)

$$\zeta = c / (2 \times \sqrt{k \times m}) = 20 / (2 \times \sqrt{600 \times 5})$$

$$= 20 / (2 \times \sqrt{3000}) = 20 / (2 \times 54.773) = 20 / 109.546 = 0.182$$

Step 3: Find damped natural frequency (ω_d)

$$\omega_d = \omega_n \times \sqrt{1 - \zeta^2} = 10.954 \times \sqrt{1 - 0.182^2}$$

$$= 10.954 \times \sqrt{1 - 0.033} = 10.954 \times 0.983 = 10.78 \text{ rad/sec}$$

Step 4: Determine the damped period (T_d)

$$T_d = 2\pi / \omega_d = 2\pi / 10.78 = 0.583 \text{ sec}$$

Step 5: Amplitude decay after time t

The amplitude at time t is given by:

$$A(t) = A_0 \times e^{-\zeta \omega_n t}$$

Initial amplitude (A_0) = 0.02 m, $t = 3$ sec

$$A(3) = 0.02 \times e^{-0.182 \times 10.954 \times 3} = 0.02 \times e^{-5.999} = 0.02 \times 0.0025 = 0.00005 \text{ m}$$

The amplitude diminishes significantly over time due to damping.

Sample Problem 3: Forced Vibration with Resonance**Problem Statement:**

A mass-spring system with mass 2 kg and spring constant 400 N/m is subjected to a harmonic force of amplitude 50 N. The damping coefficient is 10 Ns/m. Determine the steady-state amplitude of the system when the forcing frequency:

- Equals the natural frequency.
- Is doubled the natural frequency.

Solution:**Step 1: Find the natural frequency (ω_n)**

$$\omega_n = \sqrt{k/m} = \sqrt{400 / 2} = \sqrt{200} = 14.14 \text{ rad/sec}$$

Step 2: Derive the amplitude (X_{ss}) formula

The steady-state amplitude is given by:

$$X_{ss} = (F_0/m) / \sqrt{(\omega_n^2 - \omega^2)^2 + (2\zeta\omega_n\omega)^2}$$

where:

- $F_0 = 50 \text{ N}$
- $\zeta = c / (2\sqrt{km}) = 10 / (2 \times \sqrt{400 \times 2}) = 10 / (2 \times 28.28) = 0.177$

Case 1: $\omega = \omega_n = 14.14 \text{ rad/sec}$

- Calculate denominator:

$$\begin{aligned}\text{Denominator} &= \omega^2[(14.14^2 - 14.14^2)^2 + (2 \times 0.177 \times 14.14 \times 14.14)^2] = \omega^2[0 + (2 \times 0.177 \times 14.14^2)]^2 \\ &= \omega^2[0 + (2 \times 0.177 \times 200)]^2 = \omega^2[2 \times 0.177 \times 200]^2 \\ &= \omega^2[70.8]^2 = 70.8\end{aligned}$$

Mechanical Vibration Solved Examples: A Comprehensive Guide for Engineers and Students**Introduction**

Mechanical vibration solved examples serve as an essential learning tool for students and practicing engineers aiming to deepen their understanding of dynamic systems. Vibration analysis forms the backbone of many engineering disciplines, including mechanical, civil, aerospace, and automotive engineering. It involves studying the oscillatory motion of mechanical systems subjected to external or internal forces. By working through practical examples, learners can grasp complex concepts such as natural frequency, damping, and resonance, and develop the skills necessary to analyze real-world problems effectively. This article offers a detailed exploration of mechanical vibration problems, illustrating key principles through representative solved examples, thereby bridging the gap between theoretical concepts and practical applications.

Understanding the Fundamentals of Mechanical Vibration

Before diving into solved examples, it's crucial to understand the fundamental concepts that underpin mechanical vibration analysis.

What is Mechanical Vibration?

Mechanical vibration refers to oscillations about an equilibrium position of a mechanical system. These oscillations can be:

- Free Vibration: Where a system vibrates after an initial disturbance without continuous external force.
- Forced Vibration: When an external periodic force continually drives the system.
- Damped Vibration: Where energy is lost over time, typically due to friction or resistance.

Key Parameters in Vibration Analysis

- Natural Frequency (ω_n): The frequency at which a system tends to oscillate in the absence of damping or external forcing.
- Damping Ratio (ζ): A measure of how oscillations decay over time, related to energy dissipation.
- Damped Natural Frequency (ω_d): The frequency of vibration when damping is present.
- Amplitude and Phase: The magnitude and phase angle of oscillations, especially relevant in forced vibrations.

Fundamental Types of Vibration Problems

Vibration problems are generally categorized based on system characteristics:

- Single Degree of Freedom (SDOF) Systems: Simplest models, involving one mass, spring, and damper.
- Multiple Degrees of Freedom (MDOF): More complex systems with interconnected masses and elastic elements.
- Continuous Systems: Such as beams and plates, modeled with partial differential equations.

In this article, we will focus primarily on SDOF systems, as they form the foundation for understanding more complex cases.

Solved Examples in Mechanical Vibration

Example 1: Free Undamped Vibration of a SDOF System

Problem Statement:

A mass-spring system consists of a mass of 10 kg attached to a spring with a stiffness of 2000 N/m. The system is initially displaced 0.05 m from equilibrium and released without any damping. Determine:

- The natural frequency of vibration.
- The equation of motion.

Solution:

Step 1: Calculate the natural frequency (ω_n):

The formula for the natural frequency of an undamped SDOF system is:

$$\omega_n = \sqrt{\frac{k}{m}}$$

Where:

$$k = 2000 \text{ N/m}$$

$$m = 10 \text{ kg}$$

Calculating:

$$\omega_n = \sqrt{\frac{2000}{10}} = \sqrt{200} \approx 14.14 \text{ rad/sec}$$

Step 2: Write the equation of motion:

For free undamped vibration, the general solution is:

$$x(t) = A \cos(\omega_n t) + B \sin(\omega_n t)$$

Step 3: Apply initial conditions:

Initial displacement:

$$x(0) = 0.05 \text{ m} \Rightarrow x(0) = A \Rightarrow A = 0.05$$

Initial velocity:

$$v(0) = 0 \Rightarrow v(t) = -A \omega_n \sin(\omega_n t) + B \omega_n \cos(\omega_n t)$$

At $t = 0$:

$$v(0) = B \omega_n = 0 \Rightarrow B = 0$$

Final Equation:

$$x(t) = 0.05 \cos(14.14 t)$$

Conclusion:

The mass oscillates with an amplitude of 0.05 m at a natural frequency of approximately 14.14

rad/sec, with no damping or external forces.

Example 2: Damped Free Vibration of a SDOF System

Problem Statement:

Using the same mass-spring system as in Example 1, now suppose a damping coefficient of 50 Ns/m is introduced. Determine:

- The damped natural frequency (ω_d).
- The time response assuming initial displacement of 0.05 m and zero initial velocity.

Solution:

Step 1: Calculate damping ratio (ζ):

$$\zeta = \frac{c}{2 \sqrt{km}}$$

Where:

$$c = 50 \text{ Ns/m}$$

Calculating:

$$\zeta = \frac{50}{2 \times \sqrt{2000 \times 10}} = \frac{50}{2 \times 141.42} \approx \frac{50}{282.84} \approx 0.177$$

Step 2: Find the damped natural frequency (ω_d):

$$\omega_d = \omega_n \sqrt{1 - \zeta^2}$$

$$\omega_d = 14.14 \times \sqrt{1 - 0.177^2} \approx 14.14 \times 0.984 \approx 13.92 \text{ rad/sec}$$

Step 3: Write the solution:

Since initial velocity is zero:

$$x(t) = e^{-\zeta \omega_n t} \left[A \cos(\omega_d t) + B \sin(\omega_d t) \right]$$

Applying initial conditions:

$$\begin{aligned} - & \quad (x(0) = 0.05 \Rightarrow A = 0.05) \\ - & \quad (v(0) = 0 \Rightarrow v(t) = -A \zeta \omega_n \cos(\omega_d t) - A \omega_d \sin(\omega_d t) \\ & + B \omega_d e^{-\zeta \omega_n t}) \end{aligned}$$

At $(t=0)$:

$$[0 = -A \zeta \omega_n + B \omega_d \Rightarrow B = \frac{A \zeta \omega_n}{\omega_d}]$$

Calculating:

$$[B = \frac{0.05 \times 0.177 \times 14.14}{13.92} \approx \frac{0.05 \times 2.506}{13.92} \approx \frac{0.1253}{13.92} \approx 0.0090]$$

Final Equation:

$$[x(t) = e^{-0.177 \times 14.14 t} \left[0.05 \cos(13.92 t) + 0.009 \sin(13.92 t) \right]]$$

Example 3: Forced Vibration with Damping

Problem Statement:

A mass-spring-damper system with $(m=5, \text{kg})$, $(k=2000, \text{N/m})$, and damping coefficient $(c=100, \text{Ns/m})$ is subjected to a harmonic force:

$$[F(t) = 100 \sin(50 t), \text{N}]$$

Determine the steady-state amplitude of vibration.

Solution:

Step 1: Calculate system parameters:

$$[\omega_n = \sqrt{\frac{k}{m}} = \sqrt{\frac{2000}{5}} = \sqrt{400} = 20, \text{rad/sec}]$$

$$[\zeta = \frac{c}{2 \sqrt{km}} = \frac{100}{2 \times \sqrt{2000 \times 5}} = \frac{100}{2 \times \sqrt{10000}} = \frac{100}{2 \times 100} = 0.5]$$

Step 2: Find the amplitude of steady-state response:

The amplitude (X) is given by:

$$X = \frac{F_0}{m \sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}}$$

Where:

$$- (F_0 = 100 \text{ N})$$

$$- (\omega = 50 \text{ rad/sec})$$

Calculate numerator:

$$F_0 = 100$$

Calculate denominator:

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

$$(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2$$

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

Compute each term:

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

$$\omega_n^2 = 400$$

$$\omega^2 = 2500$$

$$\Rightarrow \omega_n^2 - \omega^2 = -2100$$

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

$$(2 \zeta \omega_n \omega) = 2 \times 0.5 \times 20 \times 50 = 1000$$

$$\sqrt{(\omega_n^2 - \omega^2)^2 + (2 \zeta \omega_n \omega)^2}$$

Hence,

$\sqrt{\frac{100}{5}}$

$$X = \frac{100}{5} \times \sqrt{\frac{1}{5}}$$

Question What is a common method to analyze free vibrations in a mechanical system? A common method is to use the differential equation of motion derived from Newton's second law, then solve for the natural frequencies and mode shapes, often employing methods like the characteristic equation or damping analysis. How do you determine the natural frequency of a single-degree-of-freedom system? The natural frequency is calculated using the formula $\omega_n = \sqrt{k/m}$, where k is the stiffness of the system and m is its mass. What is the significance of damping in mechanical vibrations, and how is it incorporated in solved examples? Damping reduces the amplitude of vibrations over time. In solved examples, damping is incorporated using a damping coefficient or damping ratio, leading to differential equations that include damping terms, which are then solved to find transient and steady-state responses. Can you provide an example of solving for the response of a damped harmonic oscillator? Yes. For a damped harmonic oscillator described by $m\ddot{x} + c\dot{x} + kx = 0$, the solution involves solving the characteristic equation to find roots, then expressing the displacement as $x(t) = e^{-(\zeta\omega_n)t} [A \cos(\omega_d t) + B \sin(\omega_d t)]$, where ζ is the damping ratio and ω_d is the damped natural frequency. What is the role of the frequency response function in mechanical vibration analysis? The frequency response function (FRF) describes how a system responds to sinusoidal inputs at different frequencies, allowing engineers to identify resonant frequencies and evaluate the amplitude of vibrations at those frequencies in solved examples. How do you solve for forced vibrations in a mechanical system subjected to harmonic excitation? Forced vibrations are solved by assuming a steady-state solution of the form $x(t) = X \cos(\omega t - \phi)$, substituting into the differential equation, and solving for the amplitude X and phase ϕ , often resulting in the frequency response equation. What is a typical example of a solved problem involving coupled vibrations? A typical example involves analyzing two masses connected by springs and dampers, deriving coupled differential equations, and solving them simultaneously, often by decoupling using normal modes, to find the system's vibration modes and responses. How are logarithmic decrement and damping ratio related in solved vibration problems? Logarithmic decrement (δ) measures the rate of amplitude decay in underdamped vibrations and is related to the damping ratio (ζ) by the formula $\delta = \pi / (2\zeta)$, helping to quantify damping characteristics from experimental data.

In a gear train, Gear A has 20 teeth, and Gear B has 40 teeth. If Gear A rotates clockwise at 100 RPM, what is the rotation speed and direction of Gear B?

Solution:

$$\text{Speed ratio} = \text{Number of teeth on Gear B} / \text{Number of teeth on Gear A} = 40 / 20 = 2$$

Gear B will rotate at $100 \text{ RPM} / 2 = 50 \text{ RPM}$, and due to gear engagement, the direction will be opposite (counterclockwise).
