This article provides comprehensive reinforcement answers to the key questions from Chapter 18, ensuring clarity and a thorough grasp of the subject.

Introduction to the Nature of Sound

What is Sound?

Sound is a form of energy that travels through a medium (such as air, water, or solids) in the form of vibrations or waves. It is a mechanical wave that requires a medium for propagation and cannot travel through a vacuum.

Characteristics of Sound Waves

Sound waves are characterized by:

- Frequency
- Wavelength
- Amplitude
- Speed

These properties influence how we perceive sound, including pitch, loudness, and quality.

Reinforcement Questions and Answers

Q1: What are the different types of sound waves? Explain with examples.

Sound waves are primarily classified into two types:

- **Longitudinal Waves:** These waves involve particle vibrations in the same direction as the wave propagation. Most sound waves in gases and liquids are longitudinal. For example, the sound produced by vocal cords or a ringing bell propagates as longitudinal waves.

- **Transverse Waves:** In these waves, particle vibrations are perpendicular to the direction of wave propagation. While transverse waves are common in solids (like waves on a string), pure sound waves in fluids are longitudinal and do not exhibit transverse wave behavior.

In summary, sound in gases and liquids predominantly propagates as longitudinal waves, while in solids, both longitudinal and transverse waves can occur depending on the medium's properties.

Q2: How does the speed of sound vary in different media?

The speed of sound depends on the medium's properties, primarily its density and elasticity. The general relation is:

$$\text{Speed of sound (v)} = \sqrt{\text{Elasticity} / \text{Density}}$$

- **In solids:** Sound travels fastest due to high elasticity and low density. For example, in steel, the speed is about 5000 m/s.

- **In liquids:** Speed is moderate; in water, it is approximately 1500 m/s.

- **In gases:** Speed is slowest; in air at room temperature, it is about 343 m/s.

Temperature also affects the speed in gases: higher temperatures increase the speed because they decrease the medium's density and increase elasticity.

Q3: Define frequency, wavelength, and amplitude in the context of sound waves.

These are fundamental properties of sound waves:

- **Frequency (f):** The number of wave cycles passing a point per second (Hz). Higher frequency means a higher pitch.

- **Wavelength (?):** The distance between successive crests or troughs of the wave. It is inversely proportional to frequency.

- **Amplitude:** The maximum displacement of particles from their rest position. It determines the loudness of sound; larger amplitude means louder sound.

Q4: What is the phenomenon of echo? How is it produced?

An echo is a reflected sound wave that arrives at the listener after a delay, allowing the original sound to be heard again. It is produced when sound waves reflect from a surface such as a wall or mountain.

- The sound source emits sound waves.
- These waves travel through the medium and reflect off a distant surface.
- The reflected waves return to the listener's ears after a time delay.

For an echo to be distinctly heard, the reflecting surface should be at least 17 meters away in air (assuming the speed of sound is 340 m/s), which corresponds to a delay of about 0.1 seconds.

Q5: What is the importance of the human ear in the perception of sound?

The human ear is an intricate organ that perceives sound and helps us interpret different qualities such as pitch and loudness. Its major parts include:

- **Outer Ear:** Collects sound waves and directs them into the ear canal.
- **Middle Ear:** Amplifies vibrations via the eardrum and ossicles.
- **Inner Ear:** Converts vibrations into electrical signals sent to the brain via the auditory nerve.

The ear's sensitivity allows us to distinguish between different sounds and their qualities, crucial for communication and environmental awareness.

Advanced Concepts and Applications

Q6: Explain the concept of resonance in sound.

Resonance occurs when an object naturally vibrates at its own frequency due to an external sound wave of the same frequency, leading to amplified vibrations. For example:

- When a tuning fork of a particular frequency is struck near a glass that has a natural frequency matching that of the fork, the glass may vibrate strongly and even shatter.
- Resonance is used in musical instruments, such as tuning a guitar string or designing a resonant cavity in a musical instrument to amplify sound.

Resonance enhances sound intensity when conditions are ideal, but it can also cause damage if uncontrolled, as in the case of structural failures.

Q7: How do musical instruments produce sound?

Musical instruments produce sound through various mechanisms:

- **String Instruments:** Vibrations of strings (e.g., guitar, violin).
- **Wind Instruments:** Vibrations of air columns within tubes (e.g., flute, clarinet).
- **Membrane Instruments:** Vibrations of membranes or drum skins (e.g., drums).
- **Electronic Instruments:** Use electronic oscillators to generate sound waves.

In all cases, the vibrations are transmitted to the air, producing sound waves that we perceive as musical notes.

Q8: Describe the phenomenon of Doppler Effect and its significance.

The Doppler Effect refers to the change in frequency or pitch of a sound as the source and observer move relative to each other. For example:

- If a siren approaches, the pitch appears higher; as it recedes, the pitch appears lower.

Mathematically, for a stationary observer and moving source:

$$f' = (v / (v - v_s)) f$$

where:

- f' = observed frequency
- v = speed of sound in the medium
- v_s = speed of the source
- f = actual frequency of the source

This phenomenon has applications in radar, astronomy, and medical imaging (ultrasound).

Practical Applications and Important Points

Q9: How is the speed of sound measured experimentally?

One common method involves:

- Generating a sound pulse and measuring the time taken to reflect from a known distance.
- Using the formula: **Speed = Distance / Time**.

For example, in a laboratory setup, a reflected sound wave is detected, and the distance to the reflecting surface is known. The time delay gives the speed of sound in the medium.

Q10: Why is understanding the nature of sound important?

Knowledge of the nature of sound is crucial for:

- Designing musical instruments and acoustics of auditoriums.
- Developing sound-based communication systems.
- Medical diagnostics like ultrasound imaging.
- Understanding environmental noise pollution and control.
- Navigation and detection systems such as SONAR and RADAR.

Nature of Sound Chapter 18 Reinforcement Answers

Understanding the nature of sound is fundamental to grasping many principles of physics, acoustics, and related scientific fields. Chapter 18, often dedicated to exploring this phenomenon, delves into the intricate behaviors, properties, and principles governing sound waves. Reinforcement answers for this chapter serve as vital tools to solidify comprehension, clarify complex concepts, and prepare learners for assessments. This article offers a comprehensive, analytical review of the key themes, concepts, and insights related to the nature of sound as covered in Chapter 18, with an emphasis on reinforcement answers that help deepen understanding.

Introduction to the Nature of Sound

Sound is an integral part of our daily experience, from the melodies we enjoy to the alerts that keep us safe. Fundamentally, sound is a form of energy that propagates through a medium—such as air, water, or solids—in the form of waves. The chapter on the nature of sound provides an in-depth exploration of how these waves are generated, transmitted, and perceived, along with the physical principles underlying their behavior.

Reinforcement answers related to this section typically focus on clarifying definitions, distinguishing between different types of waves, and understanding how physical parameters influence sound. For example, students might be asked to define sound, differentiate between longitudinal and transverse waves, or describe how the medium's properties affect sound propagation.

Characteristics of Sound Waves

Understanding the fundamental properties of sound waves is crucial. These characteristics include:

1. Frequency and Pitch

Frequency refers to the number of wave cycles that pass a point per second, measured in Hertz (Hz). The frequency of a sound wave determines its pitch—a high frequency corresponds to a high pitch, and vice versa. Reinforcement answers often emphasize the inverse relationship between wavelength and frequency, given by the wave equation:

$$v = \lambda \times f$$

where:

- v is the wave speed,
- λ is the wavelength,
- f is the frequency.

Students are typically asked to calculate the frequency or wavelength given the wave speed, reinforcing their grasp of wave equations.

2. Amplitude and Loudness

Amplitude measures the maximum displacement of particles in the medium during wave propagation. It correlates with the energy carried by the wave and the perceived loudness. Larger amplitudes translate to louder sounds, while smaller amplitudes produce softer sounds. Reinforcement answers often involve analyzing graphs of waveforms to determine amplitude and relate it to loudness perception.

3. Wavelength and Speed

Wavelength is the distance between successive crests or troughs. The wave's speed depends on the medium's properties, such as density and elasticity. Reinforcement questions may require students to calculate wave speed or wavelength based on given parameters.

4. Wave Types: Longitudinal vs. Transverse

Sound waves are primarily longitudinal, meaning particle displacement occurs parallel to wave propagation. Transverse waves, where displacement is perpendicular, are not typical for sound in gases but are relevant in solids. Reinforcement answers clarify these distinctions with illustrations and examples.

The Medium and Speed of Sound

The propagation of sound depends heavily on the medium's characteristics. The answers reinforce understanding of how different media affect sound speed and the implications thereof.

1. Effect of Medium Density and Elasticity

- Elasticity: The ability of a medium to return to its original shape after deformation influences sound speed. Higher elasticity generally results in faster sound transmission.
- Density: Denser media tend to slow down sound because particles are more tightly packed, requiring more force to displace.

The typical relation, expressed as:

$$v = \sqrt{\frac{E}{\rho}}$$

where:

- E is the elastic modulus,
- ρ is the density.

Reinforcement answers often include calculations demonstrating how increasing elasticity or decreasing density increases sound speed.

2. Sound Speed in Different Media

- In gases: Around 340 m/s in air at room temperature.
- In liquids: Faster than in gases, e.g., approximately 1500 m/s in water.
- In solids: Significantly faster, e.g., about 5000 m/s in steel.

Students are encouraged to compare these speeds and analyze how the properties of media

influence sound transmission.

Behavior of Sound Waves

The chapter explores how sound waves behave under various conditions, including reflection, refraction, diffraction, and interference.

1. Reflection of Sound

When sound waves encounter a boundary between two media, part of the wave is reflected. This phenomenon is evident in echoes and reverberations. Reinforcement answers often involve calculating the time delay of echoes or explaining how the angle of incidence relates to the angle of reflection.

2. Refraction of Sound

Refraction involves the bending of sound waves when passing through media of differing densities or temperatures. For example, in hot weather, sound waves bend upward, affecting how sound travels over distances. Reinforcement answers typically include applying Snell's Law, adapted for sound, to compute the change in direction.

3. Diffraction of Sound

Sound waves bend around obstacles and through openings, enabling us to hear sounds even when the source is not in direct line of sight. Answers may involve calculating the extent of diffraction based on wavelength and obstacle size, highlighting how lower-frequency sounds diffract more effectively.

4. Interference and Beats

When two sound waves of similar frequencies interact, they produce beats?periodic variations in loudness. Reinforcement exercises often involve calculating beat frequencies using:

$$f_{\text{beat}} = |f_1 - f_2|$$

and understanding the constructive and destructive interference patterns.

Resonance and Its Significance

Resonance occurs when a system oscillates with maximum amplitude at a particular frequency?the natural frequency. This phenomenon amplifies sound and is critical in many applications, from

musical instruments to engineering.

1. Conditions for Resonance

Resonance happens when the frequency of an external force matches the system's natural frequency. Reinforcement answers often include diagrams of tuning forks, musical instruments, or bridges, illustrating the effect.

2. Examples of Resonance

- Musical instruments (e.g., air columns in organ pipes)
- Architectural acoustics
- Structural failures due to resonance (e.g., Tacoma Narrows Bridge collapse)

Students are asked to analyze scenarios where resonance can be beneficial or detrimental, emphasizing the importance of controlling resonance effects.

Applications of the Nature of Sound

Understanding the physical principles of sound extends beyond theory into practical applications:

- Medical Imaging: Ultrasound utilizes high-frequency sound waves to produce images of internal organs.
- Communication: Microphones and speakers convert sound waves to electrical signals and vice versa.
- Noise Control: Designing barriers and insulation to mitigate unwanted sound.
- Sonar Technology: Navigating and detecting objects underwater using sound waves.

Reinforcement answers often include case studies or problem-solving exercises related to these applications, reinforcing real-world relevance.

Common Reinforcement Questions and Their Analysis

To cement understanding, students often encounter a range of reinforcement questions. These questions test comprehension, calculation skills, and application of principles.

Typical Question Types:

- Definition-based: What is sound? Explain the nature of longitudinal waves.
- Calculation-based: Given the wave speed and wavelength, find frequency.

Reinforcement answers act as guides, illuminating the path toward a clear and nuanced understanding of the intricate nature of sound.

Question What is the nature of sound as explained in Chapter 18? The nature of sound refers to the physical phenomenon of vibrations traveling through a medium (such as air, water, or solids) that can be heard when they reach a listener's ear. How do sound waves propagate through different media? Sound waves propagate as longitudinal waves through media like air, water, and solids by causing particles to vibrate in the direction of wave travel, transferring energy from one particle to the next. What is the difference between sound and noise according to Chapter 18? Sound is generally considered as a pleasant or meaningful vibration, whereas noise refers to unwanted or disturbing sound that causes discomfort or distraction. How does the elasticity of a medium affect the speed of sound? The greater the elasticity of the medium, the faster the sound travels through it because elastic materials restore their shape quickly after deformation, facilitating

rapid wave transmission. Why does sound require a medium to travel? Sound requires a medium because it is a mechanical wave that propagates through particle vibrations; in a vacuum, where there are no particles, sound cannot travel. What role does the density of a medium play in the speed of sound? Generally, higher density media slow down the speed of sound because the particles are more massive and resist movement, but this also depends on the medium's elasticity. How does temperature affect the speed of sound in air? Increasing the temperature of air increases the speed of sound because warmer air has molecules moving faster, allowing sound waves to propagate more quickly. What is the significance of the reinforcement answers in Chapter 18? Reinforcement answers help students consolidate their understanding of the concepts related to the nature of sound, ensuring a clearer grasp of wave properties, media, and propagation principles. How can understanding the nature of sound help in real-life applications? Understanding the nature of sound aids in designing musical instruments, improving acoustics in auditoriums, developing soundproofing materials, and enhancing communication technologies.

Key Topics and Analytical Insights

To excel in the Chapter 14 test, students must not only memorize definitions but also develop a deep understanding of the principles and their applications. Here, we analyze some of the most critical topics in detail.

Energy Forms and Conservation

Understanding Energy Types:

Energy manifests in various forms, each with unique characteristics and transformations. For example:

- Kinetic Energy: Energy of motion, dependent on mass and velocity ($KE = \frac{1}{2}mv^2$)
- Potential Energy: Stored energy due to position or configuration, such as gravitational potential energy ($PE = mgh$)
- Thermal Energy: Related to the temperature and internal motion of particles
- Chemical Energy: Stored in bonds within molecules
- Nuclear Energy: Stored in atomic nuclei
- Electromagnetic Energy: Carried by waves, including visible light, radio waves, etc.

Conservation of Energy:

This principle states that energy cannot be created or destroyed, only transformed from one form to another. For example, when a ball is dropped, potential energy converts to kinetic energy, and eventually to thermal energy through air resistance and friction.

Implication in Real-World Applications:

Understanding energy conservation is crucial in designing efficient engines, renewable energy systems, and understanding natural phenomena.

Wave Properties and Behavior

Wavelength, Frequency, and Speed:

The interrelationship between these properties is fundamental:

- $v = f \lambda$, where v is wave speed, f is frequency, and λ is wavelength.

Types of Waves:

- Transverse waves: Particles vibrate perpendicular to wave direction (e.g., waves on a string, light)
- Longitudinal waves: Particles vibrate parallel to wave direction (e.g., sound)

Wave Interactions:

- Reflection: Waves bouncing off surfaces
- Refraction: Bending of waves as they pass through different mediums
- Diffraction: Waves spreading around obstacles
- Interference: Constructive and destructive interactions

Understanding these interactions explains phenomena like rainbows, sonar operation, and the functioning of optical devices.

Sound Waves and Their Characteristics

Sound is a longitudinal wave that propagates through a medium via particle vibration. Key properties include:

- Pitch: Related to frequency; higher frequency means higher pitch.
- Loudness: Related to amplitude; larger amplitude results in louder sound.
- Speed: Depends on the medium (faster in solids, slower in gases).

Analytical questions might involve calculating the speed of sound in different materials or understanding how medium properties affect sound transmission.

Electromagnetic Spectrum and Light Waves

The electromagnetic spectrum encompasses all electromagnetic waves, from radio waves to gamma rays. Key points include:

- Wavelength and Frequency: Inversely related; longer wavelengths correspond to lower

frequencies.

- Wave Behavior: Reflection, refraction, dispersion, polarization.
- Applications: Communication (radio, television), medical imaging (X-rays), energy transfer (solar panels).

Critical Analysis:

Students should grasp how the properties of electromagnetic waves underpin modern technology, and how different wavelengths are used for specific purposes based on their energy and penetration abilities.

Practical Applications and Technological Relevance

The concepts covered in Chapter 14 are not just theoretical but have wide-ranging applications:

- Communication Technologies: Radio, television, Wi-Fi utilize electromagnetic waves.
- Medical Imaging: X-rays and ultrasound depend on wave interactions with matter.
- Energy Production: Nuclear energy harnesses nuclear reactions; solar panels convert electromagnetic radiation into electricity.
- Environmental Science: Understanding wave interactions aids in climate modeling and remote sensing.

Analytical Perspective:

Success in the test requires students to connect theoretical principles with real-world applications, demonstrating not only comprehension but also the ability to analyze and evaluate technological uses of wave and energy principles.

Strategies for Success in the Chapter 14 Test

Given the breadth and depth of topics, students should adopt comprehensive strategies:

- Master Key Definitions and Formulas: Memorize and understand how to apply formulas like $v = f \lambda$ and energy equations.

Overview of Mechanical Waves

What Are Mechanical Waves?

Mechanical waves are disturbances that travel through a medium (solid, liquid, or gas) due to the vibration of particles within that medium. Unlike electromagnetic waves, they require a medium for propagation. Examples include sound waves, water waves, and seismic waves.

Types of Mechanical Waves

- **Transverse Waves:** Particles move perpendicular to the direction of wave propagation. Example: waves on a string or surface water waves.
- **Longitudinal Waves:** Particles oscillate parallel to the wave direction. Example: sound waves in air.
- **Surface Waves:** Combine properties of both transverse and longitudinal waves, typically traveling along the interface of two media, such as water surface waves.

Core Concepts Typically Covered in Assessments

Wave Properties

- **Wavelength (λ):** The distance between successive crests or troughs.
- **Frequency (f):** How many waves pass a point per second (Hz).
- **Speed (v):** How fast the wave propagates through the medium.
- **Amplitude:** The maximum displacement of particles from their rest position, related to wave

energy.

Wave Behavior and Interactions

- **Reflection:** When a wave bounces back after hitting a boundary.
- **Refraction:** The bending of waves as they pass from one medium to another.
- **Diffraction:** Waves spreading out after passing through a narrow opening or around obstacles.
- **Interference:** When two or more waves overlap, resulting in constructive or destructive interference.

- **Compare Your Work:** After completing an assessment, compare your answers with the provided solutions to identify misconceptions.
- **Understand the Explanation:** Review detailed explanations to grasp the reasoning behind correct answers.
- **Practice Repetition:** Rework similar problems to reinforce understanding of concepts.
- **Seek Clarification:** Use assessment answers to pinpoint areas where further study or teacher assistance is needed.

For Educators

Assessment answers are invaluable tools for teachers to evaluate student comprehension. They can be used to:

- Create answer keys for grading
- Design follow-up questions that address common errors
- Identify topics that require additional instruction
- Develop practice exams and quizzes based on assessment patterns

Common Types of Questions and Their Corresponding Answers

Multiple-Choice Questions

These questions test recognition and understanding of key concepts. Example:

Question: Which of the following best describes a transverse wave?

- a) Particles oscillate parallel to wave direction
- b) Particles oscillate perpendicular to wave direction
- c) Particles oscillate randomly
- d) Particles do not oscillate

Answer: b) Particles oscillate perpendicular to wave direction

Short Answer and Calculation Problems

These require applying formulas and concepts to find unknowns. Example:

Question: A wave has a frequency of 50 Hz and a wavelength of 4 meters. What is its speed?

Solution: Using $v = f \times \lambda$, $v = 50 \text{ Hz} \times 4 \text{ m} = 200 \text{ m/s}$.

Answer: 200 meters per second

Conceptual and Explanation Questions

These assess understanding of phenomena like wave interference or the Doppler effect. Example:

Question: Explain why the frequency of a siren appears higher as an ambulance approaches you and lower as it moves away.

Answer: Due to the Doppler effect, the sound waves are compressed as the source approaches, increasing the frequency, and stretched as it recedes, decreasing the frequency.

Sample Assessment Answers for Common Questions

Question 1: What is the relationship between wave speed, frequency, and wavelength?

Answer: The relationship is given by the formula $v = f \times \lambda$. Wave speed (v) equals the frequency (f) multiplied by the wavelength (λ). This means that if two of these variables are known, the third can be calculated.

Question 2: Describe how wave reflection occurs and provide an example.

Answer: Reflection occurs when a wave encounters a boundary and bounces back into the original medium. An example is echo formation when sound waves reflect off a distant wall or mountain.

Question 3: How does the medium affect wave speed?

Answer: Wave speed depends on the properties of the medium, such as density and elasticity. Generally, waves travel faster in solids than in liquids or gases because of the greater rigidity of solids.

Addressing Common Challenges with Mechanical Waves Assessment Answers

Understanding Complex Concepts

Some students find topics like interference patterns or resonance difficult. Reviewing detailed assessment answers can clarify these concepts by providing step-by-step explanations and visual aids.

Applying Mathematical Formulas

Many assessment questions involve calculations. Practice with varied problems and consult answer keys to develop confidence in applying formulas correctly.

Types of Mechanical Waves

Mechanical waves are generally classified into two main types:

- Transverse Waves: The particle displacement is perpendicular to the wave's direction of travel (e.g., waves on a string, seismic S-waves).
- Longitudinal Waves: The particle displacement is parallel to the wave's direction (e.g., sound waves, compression waves).

Key Properties of Mechanical Waves

Understanding the following properties is crucial for solving assessment questions:

- Wavelength (λ): The distance between successive crests or troughs.
- Frequency (f): How many wave cycles pass a point per second (Hz).
- Period (T): The time it takes for one complete wave cycle (seconds).
- Wave Speed (v): How fast the wave propagates through the medium (m/s).
- Amplitude: The maximum displacement from equilibrium, related to energy transfer.
- Energy: Proportional to the square of the amplitude.

Common Types of Questions in Prentice Hall Mechanical Waves Assessments

Assessment questions often test conceptual understanding, mathematical problem-solving, and application skills. Below are common question categories and detailed approaches to solving them.

- Conceptual Questions

These questions assess your understanding of wave behaviors, properties, and principles.

Sample Question:

What is the difference between transverse and longitudinal waves?

Answer Explanation:

Transverse waves have particle displacement perpendicular to the direction of wave propagation, such as waves on a string or water waves. In contrast, longitudinal waves have particle displacement parallel to the direction of wave travel, like sound waves moving through air.

Recognizing the particle movement relative to the wave direction helps distinguish between the two.

- Calculations Involving Wave Speed, Wavelength, and Frequency

These often rely on the wave equation:

$$v = f \times \lambda$$

Where:

- v is wave speed (m/s)
- f is frequency (Hz)
- λ is wavelength (m)

Sample Problem:

A wave on a string has a frequency of 60 Hz and a wavelength of 2 meters. What is its wave speed?

Solution:

Using the wave equation:

$$v = f \times \lambda = 60 \text{ Hz} \times 2 \text{ m} = 120 \text{ m/s}$$

Assessment Tip:

Always check units and ensure they are compatible. Remember, if the question provides two of the three variables, you can easily find the third.

- Understanding and Applying the Relationship Between Period and Frequency

Recall that:

$$T = 1 / f$$

Sample Question:

If the frequency of a wave is 0.5 Hz, what is its period?

Answer:

$$T = 1 / 0.5 \text{ Hz} = 2 \text{ seconds}$$

- Wave Reflection and Transmission

Questions may involve understanding what happens when a wave encounters a boundary.

Sample Question:

When a wave reflects off a fixed end, what is the phase change?

Answer:

The wave undergoes a phase change of 180 degrees (inversion) upon reflection at a fixed end.

Analyzing and Solving Example Assessment Questions

Let's examine some typical assessment questions and walk through detailed solutions.

Example 1: Calculating Wavelength from Speed and Frequency

Question:

A sound wave travels through air at 340 m/s with a frequency of 170 Hz. What is its wavelength?

Solution:

Using $v = f \times \lambda$, rearranged as $\lambda = v / f$:

$$\lambda = 340 \text{ m/s} / 170 \text{ Hz} = 2 \text{ meters}$$

Key Point:

Remember to convert all units properly and double-check your calculations.

Example 2: Determining Wave Speed in a Rope

Question:

A wave on a rope has a wavelength of 4 meters and a period of 0.5 seconds. Find the wave's speed.

Solution:

First, find the frequency:

$$f = 1 / T = 1 / 0.5 \text{ s} = 2 \text{ Hz}$$

Then, apply $v = f \times \lambda$:

$$v = 2 \text{ Hz} \times 4 \text{ m} = 8 \text{ m/s}$$

Example 3: Interpreting Graphs of Waves

Question:

Given a graph showing displacement versus time for a wave, identify its period and frequency.

Approach:

- Find the time between two successive crests or troughs to determine the period (T).
- Calculate frequency as $f = 1 / T$.

Sample:

If the time between crests is 0.25 seconds, then:

$$T = 0.25 \text{ s}$$

$$f = 1 / 0.25 \text{ s} = 4 \text{ Hz}$$
