- Wavelength: The device's gain spectrum varies with wavelength.
- Temperature: Affects carrier dynamics and gain properties.

Key Performance Metrics

- Small-signal gain: The initial amplification at low input power.
- Saturation power: The input power level at which gain drops by 3 dB.
- Noise figure: Quantifies the added noise during amplification.

- Bandwidth: The spectral range over which the SOA provides effective gain.
- Recovery time: The time it takes the SOA to recover after saturation.

Importance of Dynamic Simulations

While static models provide insight into the steady-state characteristics of SOAs, they fall short in capturing transient phenomena such as:

- Signal switching and modulation dynamics
- Saturation and recovery behavior
- Noise and jitter characteristics
- Four-wave mixing and nonlinear effects
- Impact of high-speed data transmission on device performance

Dynamic simulations enable researchers and engineers to analyze these phenomena comprehensively, facilitating device optimization, system integration, and the development of advanced modulation formats.

Physical Models for Dynamic Simulation

Carrier Rate Equations

At the core of dynamic modeling are the carrier rate equations, which describe the temporal evolution of carrier density $N(z,t)$:

$$\frac{\partial N(z,t)}{\partial t} = \frac{J(z,t)}{qV} - \frac{N(z,t)}{\tau_N} - G(N,z,t) \cdot S(z,t)$$

]

where:

- $J(z,t)$: injection current density
- q : electronic charge
- V : active volume
- τ_N : carrier lifetime
- $G(N,z,t)$: gain coefficient dependent on carrier density
- $S(z,t)$: photon density

This differential equation captures the generation, recombination, and stimulated emission processes, forming the basis for dynamic behavior analysis.

Optical Propagation Equations

The evolution of the optical field $\mathcal{E}(z,t)$ or photon density $\mathcal{S}(z,t)$ along the propagation axis is modeled via the coupled wave equations, often simplified to the traveling-wave equations:

$$\frac{\partial \mathcal{S}(z,t)}{\partial z} + \frac{1}{v_g} \frac{\partial \mathcal{S}(z,t)}{\partial t} = \Gamma \cdot G(N,z,t) - \alpha \mathcal{S}(z,t)$$

where:

- v_g : group velocity
- Γ : optical confinement factor
- α : internal losses

These equations are coupled with the carrier rate equations and require numerical methods for solutions.

Nonlinear and Additional Effects

In high-speed and high-power regimes, additional effects must be considered:

- Spectral dependence of gain and refractive index
- Four-wave mixing (FWM)
- Self-phase modulation (SPM)
- Cross-phase modulation (XPM)
- Two-photon absorption (TPA) and free-carrier absorption (FCA)

Incorporating these nonlinearities enhances the accuracy of the models, especially for advanced modulation formats.
